

Discrete Time Series

Lecture 07

Dr. Colin Rundel

Random variable review

Mean and variance of RVs

- Expected Value

$$E(X) = \begin{cases} \sum_{\mathbf{x}} \mathbf{x} \cdot P(X = \mathbf{x}) & X \text{ is discrete} \\ \int_{-\infty}^{\infty} \mathbf{x} \cdot f(\mathbf{x}) \, d\mathbf{x} & X \text{ is continuous} \end{cases}$$

- Variance

$$\begin{aligned} \text{Var}(X) &= E\left(\left(X - E(X)\right)^2\right) = E(X^2) - E(X)^2 \\ &= \begin{cases} \sum_{\mathbf{x}} \left(\mathbf{x} - E(X)\right)^2 \cdot P(X = \mathbf{x}) & X \text{ is discrete} \\ \int_{-\infty}^{\infty} \left(\mathbf{x} - E(X)\right)^2 \cdot f(\mathbf{x}) \, d\mathbf{x} & X \text{ is continuous} \end{cases} \end{aligned}$$

Covariance of RVs

$$\text{Cov}(X, Y) = E\left(\left(X - E(X)\right)\left(Y - E(Y)\right)\right) = E(XY) - E(X)E(Y)$$

$$= \begin{cases} \sum_{\mathbf{x}} \left(\mathbf{x} - E(X)\right)\left(\mathbf{y} - E(Y)\right) \cdot P(X = \mathbf{x}, Y = \mathbf{y}) & X \text{ is discrete} \\ \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left(\mathbf{x} - E(X)\right)\left(\mathbf{y} - E(Y)\right) \cdot f(\mathbf{x}, \mathbf{y}) \, d\mathbf{x} \, d\mathbf{y} & X \text{ is continuous} \end{cases}$$

$$\text{Corr}(X, Y) = \frac{\text{Cov}(X, Y)}{\sqrt{\text{Var}(X) \text{Var}(Y)}}$$

Properties of Expected Value

- *Constant*

$$E(c) = c \text{ if } c \text{ is constant}$$

- *Constant Multiplication*

$$E(cX) = cE(X)$$

- *Constant Addition*

$$E(X + c) = E(X) + c$$

- *Addition*

$$E(X + Y) = E(X) + E(Y)$$

- *Subtraction*

$$E(X - Y) = E(X) - E(Y)$$

- *Multiplication*

$$E(XY) = E(X)E(Y)$$

if X and Y are independent

Properties of Variance

- *Constant*

$$\text{Var}(c) = 0 \text{ if } c \text{ is constant}$$

- *Constant Multiplication*

$$\text{Var}(cX) = c^2 \text{Var}(x)$$

- *Constant Addition*

$$\text{Var}(X + c) = \text{Var}(X)$$

- *Addition*

$$\text{Var}(X + Y) = \text{Var}(X) + \text{Var}(Y)$$

if X and Y are independent.

- *Subtraction*

$$\text{Var}(X - Y) = \text{Var}(X) + \text{Var}(Y)$$

if X and Y are independent.

Properties of Covariance

- *Constant*

$$\text{Cov}(X, c) = 0 \text{ if } c \text{ is constant}$$

- *Identity*

$$\text{Cov}(X, X) = \text{Var}(X)$$

- *Symmetric*

$$\text{Cov}(X, Y) = \text{Cov}(Y, X)$$

- *Distribution*

$$\text{Cov}(aX + bY, cV + dW) = ac \text{Cov}(X, V) + ad \text{Cov}(X, W) + bc \text{Cov}(Y, V) + bd$$

- *Constant Multiplication*

$$\text{Cov}(aX, bY) = ab \text{Cov}(X, Y)$$

- *Constant Addition*

$$\text{Cov}(X + a, Y + b) = \text{Cov}(X, Y)$$

Discrete Time Series

Stationary Processes

A stochastic process (i.e. a time series) is considered to be *strictly stationary* if the properties of the process are not changed by a shift in origin.

In the time series context this means that the joint distribution of $\{y_{t_1}, \dots, y_{t_n}\}$ must be identical to the distribution of $\{y_{t_1+k}, \dots, y_{t_n+k}\}$ for any value of n and k .

Weakly Stationary

Strict stationary is unnecessarily strong / restrictive for many applications, so instead we often opt for *weak stationary* which requires the following,

1. The process must have finite variance / second moment

$$E(y_t^2) < \infty \text{ for all } t$$

2. The mean of the process must be constant

$$E(y_t) = \mu \text{ for all } t$$

3. The cross moment (covariance) may only depends on the lag (i.e. $t - s$ for y_t and y_s)

$$\text{Cov}(y_t, y_s) = \text{Cov}(y_{t+k}, y_{s+k}) \text{ for all } t, s, k$$

When we say stationary in class we will almost always mean *weakly stationary*.

Autocorrelation

For a stationary time series, where $E(y_t) = \mu$ and $\text{Var}(y_t) = \sigma^2$ for all t , we define the autocorrelation at lag k as

$$\begin{aligned}\rho_k &= \text{Cor}(y_t, y_{t+k}) \\ &= \frac{\text{Cov}(y_t, y_{t+k})}{\sqrt{\text{Var}(y_t)\text{Var}(y_{t+k})}} \\ &= \frac{E((y_t - \mu)(y_{t+k} - \mu))}{\sigma^2}\end{aligned}$$

this is also sometimes written in terms of the autocovariance function (γ_k) as

$$\begin{aligned}\gamma_k &= \gamma(t, t+k) = \text{Cov}(y_t, y_{t+k}) \\ \rho_k &= \frac{\gamma(t, t+k)}{\sqrt{\gamma(t, t)\gamma(t+k, t+k)}} = \frac{\gamma(k)}{\gamma(0)}\end{aligned}$$

Covariance Structure

Based on our definition of a (weakly) stationary process, it implies a covariance of the following structure,

$$\Sigma = \begin{pmatrix} \gamma(0) & \gamma(1) & \gamma(2) & \gamma(3) & \cdots & \gamma(n-1) & \gamma(n) \\ \gamma(1) & \gamma(0) & \gamma(1) & \gamma(2) & \cdots & \gamma(n-2) & \gamma(n-1) \\ \gamma(2) & \gamma(1) & \gamma(0) & \gamma(1) & \cdots & \gamma(n-3) & \gamma(n-2) \\ \gamma(3) & \gamma(2) & \gamma(1) & \gamma(0) & \cdots & \gamma(n-4) & \gamma(n-3) \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \gamma(n-1) & \gamma(n-2) & \gamma(n-3) & \gamma(n-4) & \cdots & \gamma(0) & \gamma(1) \\ \gamma(n) & \gamma(n-1) & \gamma(n-2) & \gamma(n-3) & \cdots & \gamma(1) & \gamma(0) \end{pmatrix}$$

Example - Random walk

Let $y_t = y_{t-1} + w_t$ with $y_0 = 0$ and $w_t \sim N(0, 1)$.

Random walk

ACF + PACF

Stationary?

Is y_t stationary?

Partial Autocorrelation - pACF

Given these type of patterns in the autocorrelation we often want to examine the relationship between y_t and y_{t+k} with the (linear) dependence of y_t on y_{t+1} through y_{t+k-1} removed.

This is done through the calculation of a partial autocorrelation ($\alpha(k)$), which is defined as follows:

$$\alpha(0) = 1$$

$$\alpha(1) = \rho(1) = \text{Cor}(y_t, y_{t+1})$$

$$\vdots$$

$$\alpha(k) = \text{Cor}(y_t - P_{t,k}(y_t), y_{t+k} - P_{t,k}(y_{t+k}))$$

where $P_{t,k}(y)$ is the project of y onto the space spanned by $y_{t+1}, \dots, y_{t+k-1}$.

pACF - Calculation

Let $\rho(k)$ be the autocorrelation for the process at lag k then the partial autocorrelation at lag k will be $\phi(k, k)$ given by the Durbin-Levinson algorithm,

$$\phi(k, k) = \frac{\rho(k) - \sum_{t=1}^{k-1} \phi(k-1, t) \rho(k-t)}{1 - \sum_{t=1}^{k-1} \phi(k-1, t) \rho(t)}$$

where

$$\phi(k, t) = \phi(k-1, t) - \phi(k, k) \phi(k-1, k-t)$$

Starting with $\phi(1, 1) = \rho(1)$ we can solve iteratively for $\phi(2, 2), \dots, \phi(k, k)$.

Example - Random walk with drift

Let $y_t = \delta + y_{t-1} + w_t$ with $y_0 = 0$ and $w_t \sim N(0, 1)$.

Random walk with trend

ACF + PACF

Stationary?

Is y_t stationary?

Example - Moving Average

Let $w_t \sim N(0, 1)$ and $y_t = w_{t-1} + w_t$.

Moving Average

ACF + PACF

Stationary?

Is y_t stationary?

Autoregressive

Let $w_t \sim N(0, 1)$ and $y_t = y_{t-1} - 0.9y_{t-2} + w_t$ with $y_t = 0$ for $t < 1$.

Autoregressive

ACF + PACF

Example - Australian Wine Sales

Australian total wine sales by wine makers in bottles \leq 1 litre. Jan 1980 – Aug 1994.

```
1 aus_wine = readRDS("data/aus_wine.rds")
2 aus_wine
```

```
# A tibble: 176 × 2
```

```
  date sales
  <dbl> <dbl>
1 1980  15136
2 1980.  16733
3 1980.  20016
4 1980.  17708
5 1980.  18019
6 1980.  19227
7 1980.  22893
8 1981.  23739
9 1981.  21133
```

Time series

Basic Model Fit

Residuals

Autocorrelation Plot

Auto regressive errors

Call:

```
lm(formula = quad_resid ~ lag_12, data = d_ar)

Residual residuals - acf

Writing down the model?

So, is our EDA suggesting that we fit the following model?

$$\text{sales}_t = \beta_0 + \beta_1 t + \beta_2 t^2 + \beta_3 \text{sales}_{t-12} + \epsilon_t$$

the model we actually fit is,

$$\text{sales}_t = \beta_0 + \beta_1 t + \beta_2 t^2 + w_t$$

where

$$w_t = \delta w_{t-12} + \epsilon_t$$
